Abstract. Functions of bounded deformation (BD) arise naturally in the study of fracture and damage in a geometrically linear context. They are related to functions of bounded variation (BV), but are less well understood. We discuss here the relation to BV under additional regularity assumptions, which may require the regular part of the strain to have higher integrability or the jump set to have finite area or the Cantor part to vanish. On the positive side, we prove that BD functions which are piecewise affine on a Caccioppoli partition are in $GSBV$, and we prove that SBD^p functions are approximately continuous \mathcal{H}^{n-1} -a.e. away from the jump set. On the negative side, we construct a function which is BD but not in BV and has distributional strain consisting only of a jump part, and one which has a distributional strain consisting of only a Cantor part.

1 Introduction

The space $BD(\Omega)$ of functions of bounded deformation is characterized by the fact that the symmetric part of the distributional gradient $Eu := (Du + Du^T)/2$ is a bounded Radon measure,

$$BD(\Omega) := \{u \in L^1(\Omega; \mathbb{R}^n) : Eu \in \mathcal{M}(\Omega; \mathbb{R}_{\text{sym}}^{n \times n})\}, \quad (1.1)$$

where $\Omega \subseteq \mathbb{R}^n$ is an open set. BD constitutes the natural setting for the study of plasticity, damage and fracture models in a geometrically linear framework [34, 35, 36, 5, 29]. Despite its importance, it is not yet completely understood.

One crucial property of BD functions is that the strain can be decomposed in a part absolutely continuous with respect to the Lebesgue measure

\mathcal{L}^n , a jump part and a third part, called Cantor part,

$$Eu = e(u)\mathcal{L}^n + \frac{[u] \otimes \nu + \nu \otimes [u]}{2} \mathcal{H}^{n-1} \llcorner J_u + E^c u. \quad (1.2)$$

Here J_u is the jump set, which is a $(n-1)$ -rectifiable subset of Ω , $[u] : J_u \rightarrow \mathbb{R}^n$ is the jump of u , and ν the normal to J_u , see [3] for details. This decomposition is very similar to the one holding for the space of functions of bounded variation (BV), which is defined as the set of L^1 functions whose gradient is a bounded measure [4], but BD is strictly larger than BV . A function such that the symmetric part of the gradient is integrable, but the full gradient is not integrable, was first constructed by Ornstein in 1962 [31], a simpler construction was obtained in [19] using laminates with unbounded support, a much more general statement was then proven in [28]. In all these examples only the first term in (1.2) is nonzero. It is therefore natural to ask whether a function $u \in BD(\Omega)$ such that $e(u)$ has higher integrability may be in $BV(\Omega)$. We address this question in Section 3 below. We remark that the answer would obviously be positive if instead $Eu = e(u)\mathcal{L}^n$ with $e(u) \in L^p$, since in this case $u \in W^{1,p}$ by Korn's inequality.

In the modeling of fracture in linear elasticity one often focuses on the set of special functions of bounded deformation

$$SBD(\Omega) := \{u \in BD(\Omega) : E^c u = 0\},$$

see for example [25, 14, 33, 11, 24, 27]; here $e(u)$ is interpreted as an elastic strain, and the jump part as a fracture term. The space SBD is however only closed with respect to topologies that entail a bound stronger than L^1 on the regular part $e(u)$ of the strain, and a constraint on the \mathcal{H}^{n-1} measure of the jump set. Therefore one naturally considers the subspace SBD^p , defined for $p \in (1, \infty)$ as

$$SBD^p(\Omega) := \{u \in BD(\Omega) : E^c u = 0, e(u) \in L^p(\Omega), \mathcal{H}^{n-1}(J_u) < \infty\}, \quad (1.3)$$

see for example [7, 15, 16].

The analysis of models based on BD and SBD^p functions often requires knowledge of their fine properties, which are still not well understood. In contrast, in the BV framework fine properties are known in much more detail [4], and have proven useful for example in studying relaxation [8, 10, 9]. Correspondingly, the study of lower semicontinuity and relaxation in BD is still in its beginnings. Lower semicontinuity was studied in SBD^p by Bellettini, Coscia and Dal Maso [7] (see [26] for further results on surface integrals and related references), and more recently in BD by Rindler [32] (see [23] for

partial results). Relaxation in BD was studied in [12, 13, 20] for specific plasticity models, in [6] for autonomous functionals with linear growth defined on $W^{1,1}$, an extension to the full space BD is provided in [32]. General integral representation result have been established for certain functionals with linear growth restricted to SBD in [22]. Compactness and approximation results in SBD^p with more regular functions have been obtained in [7, 15, 16, 27].

It is therefore important to understand the relation between BD , SBD^p and BV . In this paper, we contribute to this topic in studying three different problems.

First, we show that if $u \in SBD(\Omega)$ is a piecewise rigid displacement, in the sense that the strain Eu only consists of a jump part and the total length of the jumps is finite, then $u \in GSBV(\Omega; \mathbb{R}^n)$, see Theorem 2.2 for a precise formulation. In particular, if u is bounded then $u \in SBV(\Omega; \mathbb{R}^n)$. The class of piecewise rigid displacements arises naturally in analyzing rigidity properties in the framework of linearly elastic fracture mechanics (see, for example, [18]).

Secondly, we construct a function in $SBD(\Omega) \setminus GBV(\Omega; \mathbb{R}^n)$ which has $e(u) = 0$ almost everywhere (Theorem 3.1). This is based on a modification of the construction from [19]. A variant of our construction leads to a function in $BD(\Omega) \setminus GBV(\Omega; \mathbb{R}^n)$ which has $e(u) = 0$ almost everywhere and no jump, so that $Eu = E^c u$, see Theorem 3.6.

One of the main properties of BV functions is that they are approximately continuous \mathcal{H}^{n-1} -almost everywhere away from the jump points, and not only \mathcal{L}^n -almost everywhere as any integrable function. It is still unknown if this property holds also for functions in BD . In Section 4 we show that SBD^p functions, $p > 1$, are approximately continuous at \mathcal{H}^{n-1} -almost every point away from the jump set, see Theorem 4.1.

Finally, in view of the previous results, in Section 5 we discuss the possibility that SBD^p functions are actually of bounded variation.

2 Caccioppoli-affine functions have (generalized) bounded variation

In this section we show that piecewise affine functions induced by Caccioppoli partitions have components in $GSBV$. For the theory of Caccioppoli partitions we refer to [4, Section 4.4]. In particular, for a given open set $\Omega \subset \mathbb{R}^n$ we consider a countable family $\mathcal{E} = (E_k)_k$ of sets $E_k \subseteq \Omega$ with finite

perimeter in Ω satisfying

$$\mathcal{L}^n(\Omega \setminus \cup_k E_k) = 0, \quad \mathcal{L}^n(E_i \cap E_k) = 0 \text{ for } i \neq k, \quad \sum_k \mathcal{H}^{n-1}(\partial^* E_k \cap \Omega) < \infty,$$

where $\partial^* E_k$ is the essential boundary of E_k (see [4, Definition 3.60]). The set of interfaces $J_{\mathcal{E}}$ of the Caccioppoli partition \mathcal{E} is defined as the union of the sets $\partial^* E_k \cap \Omega$. It is known that [4, Theorem 4.23].

$$\mathcal{H}^{n-1}(J_{\mathcal{E}}) = \frac{1}{2} \sum_k \mathcal{H}^{n-1}(\partial^* E_k \cap \Omega).$$

We call a function $u : \Omega \rightarrow \mathbb{R}^m$ *Caccioppoli-affine* if there exist matrices $A_k \in \mathbb{R}^{m \times n}$ and vectors $b_k \in \mathbb{R}^m$ such that

$$u(x) = \sum_k (A_k x + b_k) \chi_{E_k}(x), \quad (2.1)$$

where $(E_k)_k$ is a Caccioppoli partition of Ω .

Functions of this type have already been studied in the literature. In particular, in [18, Theorem A.1] it was proven that any function $u \in SBD(\Omega)$ with $e(u) = 0$ \mathcal{L}^n -a.e. on Ω and $\mathcal{H}^{n-1}(J_u) < \infty$ is a *piecewise rigid displacement*, which is defined as Caccioppoli-affine function with $m = n$ and the matrices A_k skew-symmetric. Moreover, piecewise rigid displacements have been employed by Dal Maso [21] to provide examples of fields in $GSBD \setminus SBD(\Omega)$. Elementary variations of such constructions prove that $SBD^p(\Omega) \setminus SBV^p(\Omega; \mathbb{R}^n) \neq \emptyset$ for every $p > 1$. Even though this is probably a well-known fact we provide an explicit construction, since we have not been able to find any reference in literature.

Example 2.1. Set $\Omega := B_1(0) \subset \mathbb{R}^n$ and for every $k \in \mathbb{N}$, choose $B_k := B_{r_k}(x_k) \subset \Omega$, so that the B_k are pairwise disjoint, the centers x_k converge to some point x_∞ , and the radii are $r_k := 2^{-k}$. We define

$$u(x) := \sum_k d_k A(x - x_k) \chi_{B_k}(x),$$

where $A = (a_{ij}) \in \mathbb{R}^{n \times n}$ with $a_{12} = -a_{21} = 1$ and $a_{ij} = 0$ otherwise, and

$$d_k := \frac{2^{nk}}{k^2}.$$

Then $u \in SBD(\Omega) \cap SBV(\Omega; \mathbb{R}^n) \cap L^\infty(\Omega; \mathbb{R}^n)$ with $e(u) = 0$ \mathcal{L}^n -a.e. and $\mathcal{H}^{n-1}(J_u) < \infty$, but for every $q > 1$ one has $\nabla u \notin L^q(\Omega; \mathbb{R}^{n \times n})$.

Nevertheless Caccioppoli-affine displacements belong to $GSBV(\Omega; \mathbb{R}^m)$. We recall that $w \in GSBV(\Omega; \mathbb{R}^m)$ if $\phi(w) \in SBV_{\text{loc}}(\Omega)$ for all $\phi \in C^1(\mathbb{R}^m)$ such that $\nabla \phi$ has compact support (cp. [4, Definition 4.26]). In the scalar case one can reduce simply to truncations (cp. [4, Remark 4.27])

Theorem 2.2. *Let $\Omega \subseteq \mathbb{R}^n$ be a bounded Lipschitz set, $u : \Omega \rightarrow \mathbb{R}^m$ be Caccioppoli-affine. Then $u \in (GSBV(\Omega))^m \subset GSBV(\Omega; \mathbb{R}^m)$ with*

$$\nabla u = A_k \quad \mathcal{L}^n\text{-a.e. on } E_k, \text{ and } \quad \mathcal{H}^{n-1}(J_u \setminus J_{\mathcal{E}}) = 0, \quad (2.2)$$

(in the last formula we use the notation introduced in (2.1)).

In particular, if $m = n$ and $u \in SBD(\Omega)$ with $e(u) = 0$ \mathcal{L}^n -a.e. on Ω and $\mathcal{H}^{n-1}(J_u) < \infty$ then $u \in (GSBV(\Omega))^m \subset GSBV(\Omega; \mathbb{R}^n)$.

Proof. It suffices to prove the first assertion in the case $m = 1$, assuming that u is a scalar map of the form $u = \sum_k (A_k \cdot x + b_k) \chi_{E_k}$, with $A_k \in \mathbb{R}^n$ and $b_k \in \mathbb{R}$.

For all $k \in \mathbb{N}$ consider $v_k := A_k \cdot x + b_k$ and $u_k := v_k \chi_{E_k}$ so that $u = \sum_k u_k$. Clearly, $u_k \in SBV(\Omega)$ with

$$Du_k = A_k \mathcal{L}^n \llcorner E_k + v_k \nu_{E_k} \mathcal{H}^{n-1} \llcorner (\partial^* E_k \cap \Omega), \quad (2.3)$$

with ν_{E_k} the generalised inner normal to E_k . For $\Phi \in C^1(\overline{\Omega}; \mathbb{R}^n)$ we use the divergence theorem to calculate

$$\int_{\Omega} u_k \operatorname{div} \Phi \, dx + \int_{\Omega} \Phi \cdot dDu_k = \int_{\partial\Omega \cap \partial^* E_k} v_k (\Phi \cdot \nu_{\partial\Omega}) \, d\mathcal{H}^{n-1},$$

where $\nu_{\partial\Omega}$ is the outer normal to $\partial\Omega$. The specific choice $\Phi \equiv A_k$ and (2.3) yield

$$|A_k|^2 \mathcal{L}^n(E_k) = - \int_{\partial^* E_k \cap \Omega} v_k A_k \cdot \nu_{E_k} \, d\mathcal{H}^{n-1} + \int_{\partial^* E_k \cap \partial\Omega} v_k A_k \cdot \nu_{\partial\Omega} \, d\mathcal{H}^{n-1},$$

and, as $\nu_{E_k} = -\nu_{\partial\Omega}$ \mathcal{H}^{n-1} -a.e. on $\partial^* E_k \cap \partial\Omega$, we conclude that

$$\int_{E_k} |\nabla u_k| \, dx = - \int_{\partial^* E_k} v_k \frac{A_k}{|A_k|} \cdot \nu_{E_k} \, d\mathcal{H}^{n-1} \leq \int_{\partial^* E_k} |v_k| \, d\mathcal{H}^{n-1}. \quad (2.4)$$

In particular, setting $w_j := \sum_{k=1}^j u_k$, it is clear that $w_j \in SBV(\Omega)$ and that

$$Dw_j = \sum_{k=1}^j Du_k.$$

Therefore, summing on $k \in \{1, \dots, j\}$ inequality (2.4), we deduce that

$$|Dw_j|(\Omega) \leq \sum_{k=1}^j |Du_k|(\Omega) \leq 2 \sum_{k=1}^j \int_{\partial^* E_k} |v_k| d\mathcal{H}^{n-1}. \quad (2.5)$$

Hence, assuming $u \in L^\infty(\Omega)$ we conclude for all $j \in \mathbb{N}$ that

$$|Dw_j|(\Omega) \leq 4\|u\|_{L^\infty(\Omega)} (\mathcal{H}^{n-1}(J_\varepsilon) + \mathcal{H}^{n-1}(\partial\Omega)).$$

In particular, $(w_j)_j$ has equi-bounded BV norm. Since $w_j \rightarrow u$ in $L^1(\Omega)$ we conclude that $u \in BV(\Omega)$. Actually, the sequence $(w_j)_k$ converges in $BV(\Omega)$ norm in view of (2.5), and being $SBV(\Omega)$ a closed subspace of $BV(\Omega)$ we infer that $u \in SBV(\Omega)$.

In the general case the conclusion $u \in GSBV(\Omega)$ follows by applying the argument above to the truncated functions $w_j^M := \sum_{k=1}^j \phi_M(u_k)$, $\phi_M(t) := t \wedge M \vee (-M)$, $M \in \mathbb{N}$, and using the chain rule formula to compute the distributional derivative. The identities in (2.2) are a consequence of (2.3).

The second assertion follows immediately using the mentioned [18, Theorem A.1]. \square

Remark 2.3. *The first assertion in Theorem 2.2 is optimal: examples of Caccioppoli affine functions in $GSBV \setminus BV(\Omega)$, though not in $BD(\Omega)$, can be easily constructed.*

3 Pure-jump BD functions not in BV

Contrary to the previous section, functions with vanishing symmetrized strain and jump set of infinite measure are not necessarily in the space $GSBV$.

Theorem 3.1. *For any nonempty open set $\Omega \subseteq \mathbb{R}^n$ there is $u \in SBD(\Omega) \cap L^\infty(\Omega; \mathbb{R}^n)$ such that $e(u) = 0$ \mathcal{L}^n -a.e., $\mathcal{H}^{n-1}(J_u) = \infty$, and $\nabla u \notin L^1(\Omega; \mathbb{R}^n)$. In particular $u \notin GBV(\Omega; \mathbb{R}^n)$.*

Our construction is based on a suitable sequence of piecewise affine functions. More precisely we consider functions which are piecewise affine on polyhedra, but not necessarily continuous. Since there are finitely many pieces and each has a boundary of finite length, these functions all belong to SBV . We recall that a convex polyhedron is a bounded set which is the intersection of finitely many half-spaces.

Definition 3.2. *For a convex polyhedron $\Omega \subset \mathbb{R}^n$ we let $PA(\Omega)$ be the set of functions $u : \Omega \rightarrow \mathbb{R}^n$ for which there is a decomposition of Ω into finitely many convex polyhedra such that u is affine on each of them.*

The next Lemma gives the basic construction step, which corresponds to the lamination used in [19].

Lemma 3.3. *Let $u \in PA(\Omega)$, $A, B \in \mathbb{R}^{n \times n}$ with $\text{rank}(A - B) = 1$, $\lambda \in (0, 1)$, $C := \lambda A + (1 - \lambda)B$, $\omega := \{x \in \Omega : Du(x) = C\}$. For every $\varepsilon > 0$ there is $v \in PA(\Omega)$ such that $v = u$ on $\Omega \setminus \omega$, $Dv \in \{A, B\}$ \mathcal{L}^n -a.e. in ω , $\mathcal{L}^n(\{x \in \omega : Dv(x) = A\}) = \lambda \mathcal{L}^n(\omega)$, and*

$$\|u - v\|_{L^\infty(\Omega, \mathbb{R}^n)} \leq \varepsilon, \quad \int_{J_v \cap \Omega} |[v]| d\mathcal{H}^{n-1} \leq \varepsilon + \int_{J_u \cap \Omega} |[u]| d\mathcal{H}^{n-1}.$$

Proof. Let $\omega_1, \dots, \omega_k$ be the polyhedra where $Du = C$. Given ω_j , let $w_j \in \text{Lip}(\mathbb{R}^n; \mathbb{R}^n)$ be a function with $Dw_j \in \{A, B\}$ \mathcal{L}^n -a.e. in ω_j and

$$\|w_j - u\|_{L^\infty(\omega_j, \mathbb{R}^n)} \leq \varepsilon \min \left\{ 1, \frac{1}{4k\mathcal{H}^{n-1}(\partial\omega_j)} \right\}.$$

To construct w_j , let $a \in \mathbb{R}^n$ and $\nu \in S^{n-1}$ be such that $A = C + (1 - \lambda)a \otimes \nu$, and set $w_j(x) := u(x) + N^{-1}ah_\lambda(Nx \cdot \nu)$, where $h_\lambda \in \text{Lip}(\mathbb{R})$ is the 1-periodic function which obeys $h_\lambda(0) = 0$, $h'_\lambda = 1 - \lambda$ on $(0, \lambda)$, $h'_\lambda = -\lambda$ on $(\lambda, 1)$ and N is sufficiently large (see for example [30, Lemma 4.3] or [19, Section 2 and Lemma 3] for details).

By translation we can ensure that the volume fractions are the stated ones. Indeed, let $S_A := \{x \in \mathbb{R}^n : Dw_j = A\}$ and ν as above. Then Fubini's theorem gives

$$\int_0^1 \mathcal{L}^n(\omega_j \cap (S_A - t\nu)) dt = \int_{\mathbb{R}^n} \left[\chi_{\omega_j}(y) \int_0^1 \chi_{S_A}(y + t\nu) dt \right] dy = \lambda \mathcal{L}^n(\omega_j),$$

where the last equality follows from the fact that χ_{S_A} is $1/N$ -periodic in the direction ν and $\chi_{S_A} = 1$ on strips each of length λ/N . Choosing a suitable t through the mean value theorem, the conclusion follows setting $v(x) := w_j(x + t\nu)$ on ω_j . \square

In our argument we shall iteratively apply Lemma 3.3 above to increase the contribution of the skew-symmetric part of the gradient without changing the contribution of the symmetric part. In order to be sure that no Cantor term in the distributional derivative is created, we stop the process after finitely many steps, and introduce an additional iteration later. To treat the remainder zones where the piecewise affine function has symmetric gradient, we approximate it with piecewise constant functions.

Lemma 3.4. *Let ω be a convex polyhedron, and let $u : \omega \rightarrow \mathbb{R}^n$ be affine. For every $\varepsilon > 0$ the following holds:*

(i) There is $v \in PA(\omega)$ such that $\|u - v\|_{L^\infty(\omega, \mathbb{R}^n)} \leq \varepsilon$, $\nabla v = 0$ \mathcal{L}^n -a.e., and

$$|Dv|(\omega) \leq n|Du|(\omega). \quad (3.1)$$

(ii) There is $v \in BV \cap C^0(\omega; \mathbb{R}^n)$ such that $\|u - v\|_{L^\infty(\omega, \mathbb{R}^n)} \leq \varepsilon$, $\nabla v = 0$ \mathcal{L}^n -a.e., and $Dv = D^c v$ with $|Dv|(\omega) \leq n|Du|(\omega)$.

Proof. Let $u(x) = Ax + b$ on ω . For $\delta > 0$ we set

$$v^\delta(x) := \sum_i A e_i \left\lfloor \frac{x_i}{\delta} \right\rfloor \delta + b,$$

where $\lfloor \alpha \rfloor$ denotes the integer part of $\alpha \in \mathbb{R}$. It is easy to see that $\|u - v^\delta\|_{L^\infty(\omega, \mathbb{R}^n)} \leq \|A\|n\delta$ and

$$\limsup_{\delta \rightarrow 0} |Dv^\delta|(\omega) \leq \sum_i |A e_i| \mathcal{L}^n(\omega) \leq \sqrt{n} \|A\| \mathcal{L}^n(\omega) = \sqrt{n} |Du|(\omega).$$

Taking δ sufficiently small the proof is concluded.

To prove the second assertion we let $\Psi \in C^0([0, 1]; [0, 1])$ be the usual Cantor staircase, with $\Psi(0) = 0$, $\Psi(1) = 1$, $\Psi' = 0$ \mathcal{L}^1 -almost everywhere, and define

$$v^\delta(x) := \sum_i A e_i \delta \left(\left\lfloor \frac{x_i}{\delta} \right\rfloor + \Psi \left(\frac{x_i}{\delta} - \left\lfloor \frac{x_i}{\delta} \right\rfloor \right) \right) + b.$$

□

We are now ready to provide the main step in our argument.

Lemma 3.5. *Let Ω be a convex polyhedron and let $M > 1$. Then there is $u \in PA(\Omega)$ such that $\|u\|_{L^\infty(\Omega, \mathbb{R}^n)} \leq c$, $e(u) = 0$ \mathcal{L}^n -a.e., $u = 0$ in a neighborhood of $\partial\Omega$, $|Eu|(\Omega) \leq 1/M$, and $\|\nabla u\|_{L^1(\Omega, \mathbb{R}^{n \times n})} \geq M$. The constant c depends only on the dimension n .*

Proof. We define, for $k \in \mathbb{N}$, the matrices $A_k, B_k, C_k \in \mathbb{R}^{n \times n}$ by

$$A_k := \begin{pmatrix} 0 & 2^k \\ 2^k & 0 \end{pmatrix}, \quad B_k := \begin{pmatrix} 0 & 2^k \\ -2^k & 0 \end{pmatrix}, \quad C_k := \begin{pmatrix} 0 & 2^k \\ 2^{k+1} & 0 \end{pmatrix},$$

with the other entries vanishing if $n > 2$. We construct inductively a sequence of functions $u_k \in PA(\Omega)$ and sets $\omega_k \subset \Omega$, with Ω_k a finite union of convex polyhedra, such that $\Omega_k := \{x \in \Omega : Du_k = A_k\}$ for every k and $e(u_k) = 0$ \mathcal{L}^n -a.e. on $\Omega \setminus \Omega_k$.

We start with a convex polyhedron $\Omega_0 \subset\subset \Omega$ with $\mathcal{L}^n(\Omega_0) \leq 1$ and the function $u_0 := \chi_{\Omega_0} A_0 x$.

In order to construct (u_{k+1}, Ω_{k+1}) from (u_k, Ω_k) , we observe that

$$A_k = \frac{1}{3}B_k + \frac{2}{3}C_k \quad \text{and} \quad \text{rank}(B_k - C_k) = 1.$$

We define \hat{u}_k by Lemma 3.3, with $\varepsilon = 2^{-k}$, $\omega = \Omega_k$, and $C = A_k$. We set $\hat{\Omega}_k := \{x \in \Omega : D\hat{u}_k(x) = C_k\}$ and note that $\hat{\Omega}_k \subset \Omega_k$ and $\mathcal{L}^n(\hat{\Omega}_k) = \frac{2}{3}\mathcal{L}^n(\Omega_k)$. Since

$$C_k = \frac{3}{4}A_{k+1} + \frac{1}{4}(-B_{k+1}) \quad \text{and} \quad \text{rank}(A_{k+1} + B_{k+1}) = 1,$$

we can apply Lemma 3.3 again to \hat{u}_k , with the same ε , $\omega = \hat{\Omega}_k$, and $C = C_k$, to obtain $u_{k+1} \in PA(\Omega)$ such that, with $\Omega_{k+1} := \{x \in \Omega : Du_{k+1}(x) = A_{k+1}\} \subset \hat{\Omega}_k$, it holds $e(u_{k+1}) = 0$ on $\Omega \setminus \Omega_{k+1}$, $\mathcal{L}^n(\Omega_{k+1}) = \frac{1}{2}\mathcal{L}^n(\Omega_k) = 2^{-(k+1)}\mathcal{L}^n(\Omega_0)$,

$$\int_{\Omega \cap J_{u_{k+1}}} |[u_{k+1}]| d\mathcal{H}^{n-1} \leq 2 \cdot 2^{-k} + \int_{\Omega \cap J_{u_k}} |[u_k]| d\mathcal{H}^{n-1}, \quad (3.2)$$

and

$$\begin{aligned} \int_{\Omega \setminus \Omega_{k+1}} |\nabla u_{k+1}| dx &= \int_{\Omega \setminus \Omega_k} |\nabla u_k| dx + \frac{1}{3}\mathcal{L}^n(\Omega_k) |B_k| + \frac{1}{6}\mathcal{L}^n(\Omega_k) |B_{k+1}| \\ &= \int_{\Omega \setminus \Omega_k} |\nabla u_k| dx + \frac{2}{3}\sqrt{2}\mathcal{L}^n(\Omega_0). \end{aligned} \quad (3.3)$$

Therefore, in view of (3.2) and (3.3), for all k we conclude

$$|Eu_k|(\Omega) \leq |A_k| \mathcal{L}^n(\Omega_k) + \sum_k 2 \cdot 2^{-k} + \int_{\partial\Omega_0} |A_0 x| d\mathcal{H}^{n-1} \leq c \quad (3.4)$$

and $\|\nabla u_k\|_{L^1(\Omega, \mathbb{R}^{n \times n})} \rightarrow \infty$.

Let $\{\Omega_k^i\}_{i=1}^N$ be the set of polyhedra which composes Ω_k , and let v_k^i be the function provided by Lemma 3.4(i) applied to u_k on Ω_k^i with $\varepsilon_i := \min \left\{ 1, 1/(N \mathcal{H}^{n-1}(\partial\Omega_k^i)) \right\}$. Recall that $\|u_k - v_k^i\|_{L^\infty(\Omega_k^i, \mathbb{R}^n)} \leq \varepsilon_i$.

We define $w_k := u_k \chi_{\Omega \setminus \Omega_k} + \sum_{i=1}^N v_k^i \chi_{\Omega_k^i}$. Note that $w_k \in PA(\Omega)$, $\nabla w_k =$

$\nabla u_k \chi_{\Omega \setminus \Omega_k}$, $e(w_k) = 0$ \mathcal{L}^{n-1} -a.e. on Ω , and

$$\begin{aligned} \int_{J_{w_k} \cap \overline{\Omega_k}} |[w_k]| d\mathcal{H}^{n-1} &= \sum_{i=1}^N \int_{J_{v_k^i} \cap \Omega_k^i} |[v_k^i]| d\mathcal{H}^{n-1} + \sum_{i=1}^N \int_{\partial \Omega_k^i} |[w_k]| d\mathcal{H}^{n-1} \\ &\stackrel{(3.1)}{\leq} n |Du_k|(\Omega_k) + \sum_{i=1}^N \|u_k - v_k^i\|_{L^\infty(\Omega_k^i, \mathbb{R}^n)} \mathcal{H}^{n-1}(\partial \Omega_k^i) + \int_{\partial \Omega_k} |[u_k]| d\mathcal{H}^{n-1} \\ &\leq c \mathcal{L}^n(\Omega_0) + 1 + \int_{J_{u_k} \cap \Omega} |[u_k]| d\mathcal{H}^{n-1} \leq c, \end{aligned} \quad (3.5)$$

for some constant c independent from k thanks to (3.2).

In conclusion by (3.4) and (3.5)

$$|Ew_k|(\Omega) \leq |Eu_k|(\Omega \setminus \overline{\Omega_k}) + \int_{J_{w_k} \cap \overline{\Omega_k}} |[w_k]| d\mathcal{H}^{n-1} \leq c,$$

for a constant c independent from k (and M). The function $w_k/(cM)$ has the stated properties for k sufficiently large. \square

We are now ready to prove the main result of the section.

Proof of Theorem 3.1. Let $\{Q_k\}_{k \in \mathbb{N}}$ be a family of countably many disjoint cubes contained in Ω . For each of them let u_k be the function constructed in Lemma 3.5 above, using $M := 2^k$. We set $u := u_k$ in Q_k , $u := 0$ on the rest. Note that the sequence $(\sum_{k=1}^j u_k \chi_{Q_k})_j$ converges in the BD norm to u as $|Eu_k|(Q_k) \leq 2^{-k}$. Therefore, $u \in SBD(\Omega)$, $e(u) = 0$ \mathcal{L}^n -a.e., $|Eu|(\Omega) = \sum_k |Eu|(Q_k) \leq 2$ and

$$\|\nabla u\|_{L^1(\Omega, \mathbb{R}^{n \times n})} = \sum_k \|\nabla u_k\|_{L^1(Q_k, \mathbb{R}^{n \times n})} \geq \sum_k 2^k = \infty.$$

Finally, $u \in L^\infty(\Omega; \mathbb{R}^n)$ by Lemma 3.5, thereby $u \notin GBV(\Omega; \mathbb{R}^n)$. \square

A slight modification of the previous construction provides a function u in $BD \setminus GBV$ for which $Eu = E^c u$.

Theorem 3.6. *For any nonempty open set $\Omega \subseteq \mathbb{R}^n$ there is $u \in BD(\Omega) \cap L^\infty(\Omega; \mathbb{R}^n)$ such that $Eu = E^c u$ and $\nabla u \notin L^1(\Omega; \mathbb{R}^n \times \mathbb{R}^n)$. In particular $u \notin GBV(\Omega; \mathbb{R}^n)$.*

Proof. The proof is similar to the one of Theorem 3.1, therefore we only highlight the significant changes in the construction. For notational simplicity we focus on the two-dimensional situation with $\Omega = (0, 1)^2$.

We introduce first cut-off functions whose gradient only has a Cantor part. Given $\ell > 0$ and $\delta \in (0, \ell/2)$, we define $\psi_{\ell, \delta} : [-\ell, \ell] \rightarrow [0, 1]$ to be

$$\psi_{\ell, \delta}(t) := \begin{cases} 1 & t \in [-\ell + \delta, \ell - \delta], \\ \Psi\left(\frac{\ell - |t|}{\delta}\right) & \text{otherwise,} \end{cases}$$

where $\Psi : [0, 1] \rightarrow [0, 1]$ is the Cantor staircase as in the proof of Lemma 3.4. For a rectangle $R = [-a, a] \times [-b, b]$ we set

$$\psi_{R, \delta}(x_1, x_2) := \psi_{a, \delta}(x_1) \psi_{b, \delta}(x_2).$$

Note that $\psi_{R, \delta} \in BV \cap C^0(R)$ with

$$D\psi_{R, \delta} = D^c\psi_{R, \delta} \quad \text{and} \quad |D^c\psi_{R, \delta}|(R) \leq \mathcal{H}^1(\partial R).$$

Moreover, $\psi_{R, \delta} = 1$ on $[-a + \delta, a - \delta] \times [-b + \delta, b - \delta]$, $\psi_{R, \delta}|_{\partial R} = 0$ so that its extension to 0 on R^c provides a function $BV \cap C^0(\mathbb{R}^2)$ without altering the total variation.

We fix $\gamma > 0$. We perform the same iterative construction as in Lemma 3.5. We start with $\Omega_0 = (0, 1)^2$ and $u_0 = A_0 x$. At step k we use Lemma 3.3 to construct from u_{k-1} and Ω_{k-1} the functions \hat{u}_k and u_k , and the sets Ω_k and $\hat{\Omega}_k$. However, at the k -th step we apply Lemma 3.3 with $\varepsilon_k = 2^{-k} \gamma \min\{1, 1/\mathcal{H}^1(\partial\hat{\Omega}_k^i)\}$, where $\{\Omega_k^i\}_{i=1}^{N_k}$ and $\{\hat{\Omega}_k^i\}_{i=1}^{M_k}$ are the polyhedra composing Ω_k and $\hat{\Omega}_k$, respectively. This concludes the construction of u_k and Ω_k . We remark that for each k the $(\Omega_k^i)_i$ are disjoint congruent rectangles, and analogously the $(\hat{\Omega}_k^i)_i$.

We now construct a sequence of modified functions U_k , where each jump is replaced by a continuous Cantor staircase. To do this, at each k we consider the Cantor-type cut-off functions $\psi_k := \sum_i \psi_{\Omega_k^i, \delta_k}$ and $\hat{\psi}_k := \sum_i \hat{\psi}_{\hat{\Omega}_k^i, \delta_k}$, where $\delta_k > 0$ will be suitably chosen below. We set $U_0 := u_0$ and

$$\begin{cases} \hat{U}_k := (1 - \psi_k)U_k + \psi_k \hat{u}_k & \text{for } k \geq 0, \\ U_k := (1 - \hat{\psi}_{k-1})\hat{U}_{k-1} + \hat{\psi}_{k-1}u_k & \text{for } k \geq 1. \end{cases} \quad (3.6)$$

Finally, the truncation step at the end is different. We let v_k^i be the function provided by Lemma 3.4(ii) applied to u_k on Ω_k^i with $\varepsilon_k = \min\left\{1, 1/(N_k \mathcal{H}^1(\partial\Omega_k^i))\right\}$. Recall that $\|u_k - v_k^i\|_{L^\infty(\Omega_k^i, \mathbb{R}^n)} \leq \varepsilon_k$ and $Dv_k^i = D^c v_k^i$. We extend v_k^i to 0 on $\Omega \setminus \Omega_k^i$ and set $v_k := \sum_i v_k^i$.

Let then

$$w_k := (1 - \psi_k)U_k + \psi_k v_k.$$

By [4, Example 3.97], $w_k \in BV \cap C^0(\Omega_0; \mathbb{R}^2)$, furthermore by construction $Dw_k = \nabla w_k \mathcal{L}^2 \llcorner \Omega_0 + D^c w_k$ with ∇w_k skew-symmetric \mathcal{L}^2 -a.e. in Ω_0 , therefore $Ew_k = E^c w_k$. More precisely, the chain-rule formula yields

$$D^c w_k = (1 - \psi_k) D^c U_k + \psi_k D^c v_k + (v_k - U_k) \otimes D^c \psi_k. \quad (3.7)$$

In what follows we shall estimate separately the total variations of the three terms in (3.7). To this aim we first note that in view of (3.6) we get

$$\|u_k - U_k\|_{L^\infty(\Omega, \mathbb{R}^n)} \leq 2 \sum_{j=0}^k \varepsilon_j \leq \frac{4\gamma}{\mathcal{H}^1(\partial \hat{\Omega}_k^i)} =: \sigma_k.$$

To bound the first term in (3.7) we notice that for some positive constant c independent from k we have

$$|D^c U_k|(\Omega_i^k) \stackrel{(3.6)}{\leq} |D^c U_{k-1}|(\Omega_i^k) + c \sigma_{k-1} \mathcal{H}^1(\partial \Omega_{k-1}^i) + c \sigma_k \mathcal{H}^1(\partial \hat{\Omega}_k^i).$$

By summing over i we get

$$|(1 - \psi_k) D^c U_k|(\Omega_0) \leq c \gamma N_k.$$

From Lemma 3.4(ii) we infer that

$$|\psi_k D^c v_k|(\Omega_0) \leq |D^c v_k|(\Omega_k) \leq 2 |Du_k|(\Omega_k) = 2 |Eu_k|(\Omega_k) \stackrel{(3.4)}{\leq} c.$$

We turn to the last term of (3.7). By the triangle inequality

$$|(v_k - U_k) \otimes D^c \psi_k|(\Omega_k^i) \leq \|v_k - U_k\|_{L^\infty(\Omega_i^k, \mathbb{R}^n)} |D^c \psi_k|(\Omega_i^k) \leq (\varepsilon_k + \sigma_k) \mathcal{H}^1(\partial \Omega_k^i).$$

Therefore

$$|(v_k - U_k) \otimes D^c \psi_k|(\Omega_0) = |(v_k - U_k) \otimes D^c \psi_k|(\Omega_k) \leq c(1 + \gamma N_k).$$

Collecting terms, we conclude that

$$|D^c w_k|(\Omega_0) \leq c(1 + \gamma N_k). \quad (3.8)$$

Finally, by arguing as in (3.3) taking into account the definitions in (3.6) we infer that

$$\begin{aligned} \int_{\Omega \setminus \Omega_k} |\nabla w_k| dx &= \int_{\Omega \setminus \Omega_k} |\nabla U_k| dx \geq \int_{\Omega \setminus \Omega_{k-1}} |\nabla U_{k-1}| dx \\ &\quad + \|B_k\| \mathcal{L}^2(\{\hat{\psi}_{k-1} = 1\} \setminus \Omega_k) + |B_{k-1}| \mathcal{L}^2(\{\psi_{k-1} = 1\} \setminus \hat{\Omega}_{k-1}) \\ &\geq \int_{\Omega \setminus \Omega_{k-1}} |\nabla U_{k-1}| dx + \frac{1}{\gamma} (|B_k| + |B_{k-1}|) \mathcal{L}^2(\Omega_{k-1}), \end{aligned}$$

by suitably choosing δ_k in the definition of ψ_j and $\hat{\psi}_j$, $0 \leq j \leq k$. Here B_k is the matrix defined in the proof of Lemma 3.5. In particular, we conclude that $\|\nabla w_k\|_{L^1(\Omega, \mathbb{R}^{2 \times 2})} \rightarrow \infty$.

Choosing k_* large enough to have $\|\nabla w_{k_*}\|_{L^1(\Omega_0, \mathbb{R}^{2 \times 2})} > c M^2$, the function $z := w_{k_*}/(c M)$ satisfies $\|\nabla z\|_{L^1(\Omega_0, \mathbb{R}^{2 \times 2})} > M$, and choosing $\gamma = 1/N_{k_*}$ the bound (3.8) gives

$$|E^c z|(\Omega_0) \leq \frac{1}{M}.$$

To conclude we remark that by the definitions in (3.6) we have $z|_{\partial\Omega_0} = u_0|_{\partial\Omega_0}$. Therefore repeating the same construction on a countable family of disjoint closed cubes and choosing $M = 2^{-j}$ we obtain a function with the properties given in the statement. \square

4 Continuity away from fractures

Let $u \in BD(\Omega)$, with Ω open. We say that $x \in \Omega$ is a point of approximate continuity of u if there is $\tilde{u}(x)$ such that

$$\lim_{r \rightarrow 0} \frac{1}{\mathcal{L}^n(B_r)} \int_{B_r(x)} |u(y) - \tilde{u}(x)| dy = 0.$$

We denote by S_u the set of points $x \in \Omega$ which are not points of approximate continuity. Since $u \in L^1(\Omega; \mathbb{R}^n)$, one immediately has $\mathcal{L}^n(S_u) = 0$.

We say that $x \in \Omega$ is a jump point of u if there are two vectors $u_+ \neq u_- \in \mathbb{R}^n$ and a normal $\nu \in S^{n-1}$ such that

$$\lim_{r \rightarrow 0} \frac{1}{\mathcal{L}^n(B_r)} \int_{B_r^+(x)} |u(y) - u_+| dy = \lim_{r \rightarrow 0} \frac{1}{\mathcal{L}^n(B_r)} \int_{B_r^-(x)} |u(y) - u_-| dy = 0,$$

where $B_r^\pm(x) = B_r(x) \cap \{\pm(y - x) \cdot \nu > 0\}$. Obviously $J_u \subset S_u$. If $u \in BV$ it is well known that $\mathcal{H}^{n-1}(S_u \setminus J_u) = 0$, see, for example, [4].

We further define Θ_u as the set of points $x \in \Omega$ such that

$$\limsup_{r \rightarrow 0} \frac{|Eu|(B_r(x))}{r^{n-1}} > 0.$$

The set Θ_u is $(n - 1)$ -rectifiable, $J_u \subset \Theta_u$, and $\mathcal{H}^{n-1}(\Theta_u \setminus J_u) = 0$, see [3, Prop. 3.5].

The main result of the section is the following theorem concerning the size of the set $S_u \setminus J_u$ when the function u belongs to $SBD^p(\Omega)$.

Theorem 4.1. *If $u \in SBD^p(\Omega)$ for some $p > 1$, with $\Omega \subset \mathbb{R}^n$ open, then $\mathcal{H}^{n-1}(S_u \setminus J_u) = 0$.*

The proof uses Lemma 4.2 and Lemma 4.4 below. The first is a consequence of the Korn-Poincaré inequality for SBD^p functions proven in [17] and states that a function $u \in SBD$ with a small jump set can be approximated by an affine function away from a special set, with an error depending only on $e(u)$.

Lemma 4.2. *There is $\eta > 0$, depending only on n , such that the following holds. For any $r > 0$ and $u \in SBD(B_r)$ such that $\mathcal{H}^{n-1}(J_u) < \eta r^{n-1}$ there are a set $\omega \subset B_r$ and an affine function $\varphi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ such that*

$$\mathcal{L}^n(\omega) \leq \frac{1}{2^{n+3}} \mathcal{L}^n(B_r)$$

and

$$\int_{B_r \setminus \omega} |u - \varphi| dx \leq c r \int_{B_r} |e(u)| dx.$$

Proof. This follows from Theorem 1 of [17]. \square

The next lemma is used in the proof of Lemma 4.4 below. It shows that it is possible to control the L^∞ -norm of an affine function through its L^1 -norm out of a special set.

Lemma 4.3. *Let $\omega \subset B := B_r(y)$ satisfy*

$$\mathcal{L}^n(\omega) \leq \frac{1}{4} \mathcal{L}^n(B) \tag{4.1}$$

and let $\varphi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ be an affine function. Then

$$\mathcal{L}^n(B) \|\varphi\|_{L^\infty(B, \mathbb{R}^n)} \leq c \|\varphi\|_{L^1(B \setminus \omega, \mathbb{R}^n)}, \tag{4.2}$$

where the constant c depends only on the dimension n .

Proof. By a scaling argument it is sufficient to prove the statement when $B = B_1$. First note that for sufficiently small $\delta > 0$ one has for every $i = 1, \dots, n$

$$\mathcal{L}^n(B \cap (B + \delta e_i)) \geq \frac{3}{4} \mathcal{L}^n(B).$$

Hence the set $E_i := (B \setminus \omega) \cap ((B \setminus \omega) + \delta e_i)$ satisfies

$$\mathcal{L}^n(E_i) \geq \frac{3}{4} \mathcal{L}^n(B) - 2 \mathcal{L}^n(\omega) \geq \frac{1}{4} \mathcal{L}^n(B). \tag{4.3}$$

Estimating the translation for an affine map $\varphi(x) = Ax + b$ one gets

$$\delta |Ae_i| \mathcal{L}^n(E_i) = \int_{E_i} |\varphi(x) - \varphi(x - \delta e_i)| dx \leq 2 \int_{B \setminus \omega} |\varphi| dx$$

and therefore by (4.3)

$$|A| \leq \frac{8\sqrt{n}}{\delta \mathcal{L}^n(B)} \|\varphi\|_{L^1(B \setminus \omega, \mathbb{R}^n)}. \quad (4.4)$$

The constant b can be estimated using (4.4) and (4.1)

$$\begin{aligned} \mathcal{L}^n(B \setminus \omega)b &\leq \|\varphi - \varphi(0)\|_{L^1(B \setminus \omega, \mathbb{R}^n)} + \|\varphi\|_{L^1(B \setminus \omega, \mathbb{R}^n)} \\ &\leq \frac{\mathcal{L}^n(B \setminus \omega)}{\mathcal{L}^n(B)} \left(\frac{8\sqrt{n}}{\delta} + \frac{4}{3} \right) \|\varphi\|_{L^1(B \setminus \omega, \mathbb{R}^n)}. \end{aligned} \quad (4.5)$$

Formula (4.2) follows from (4.4) and (4.5). \square

The following lemma refines the classical estimates for the $(n-1)$ -dimensional density in a particular case.

Lemma 4.4. *Let $f \in L^p(\mathbb{R}^n)$, for some $p > 1$, and*

$$F := \left\{ x \in \mathbb{R}^n : \sum_{k \in \mathbb{N}} \frac{1}{r_k^{n-1}} \int_{B_{r_k}(x)} |f| dy = \infty \right\}$$

where $r_k = 2^{-k}$. Then $\mathcal{H}^{n-1}(F) = 0$. If additionally $p > n$ then $F = \emptyset$.

Remark 4.5. *To see that $p > 1$ is required one can consider $f(x) := \chi_{B_{1/2}}(x)/(x_n \ln^2(1/x_n))$.*

Proof. We start from the second statement. From $\|f\|_{L^1(B_r)} \leq r^{n/p'} \|f\|_{L^p(\mathbb{R}^n)}$, where $1/p' = 1 - 1/p$, one deduces, for any $x \in \mathbb{R}^n$,

$$\sum_k \frac{1}{r_k^{n-1}} \int_{B_{r_k}(x)} |f| dy \leq \sum_k \frac{r_k^{n/p'}}{r_k^{n-1}} \|f\|_{L^p(\mathbb{R}^n)} = \|f\|_{L^p(\mathbb{R}^n)} \sum_k 2^{k(n-p)/p}.$$

If $p > n$ the last series converges and therefore $x \notin F$.

We now turn to the first statement and assume $p \in (1, n]$. By Lebesgue's differentiation theorem one has $\mathcal{L}^n(F) = 0$.

Fix $\delta > 0$. For every $x \in F$ there is $k(x) \in \mathbb{N}$ such that $r_{k(x)} < \delta$ and

$$\int_{B_{r_{k(x)}}(x)} |f| dy \geq \frac{r_{k(x)}^{n-1}}{k(x)^2}, \quad (4.6)$$

otherwise the series would converge. By Vitali's $5r$ -covering lemma, there is a family $G = \{B_{\rho_j}(x_j) : j \in \mathbb{N}\}$ of disjoint balls, with $\rho_j = r_{k(x_j)}$ and $k_j =$

$k(x_j)$, such that $F \subset \bigcup_j B_{5\rho_j}(x_j)$. Then by the definition of the Hausdorff measure

$$\mathcal{H}_{10\delta}^{n-1}(F) \leq c \sum_j (5\rho_j)^{n-1}. \quad (4.7)$$

By (4.6) and by Hölder's inequality, we obtain

$$\rho_j^{n-1} \leq k_j^2 \int_{B_{\rho_j}(x_j)} |f| dy \leq c \|f\|_{L^p(B_{\rho_j}(x_j))} k_j^2 \rho_j^{n/p'}.$$

For all $M \in \mathbb{N}$, using Hölder's inequality and the fact that the balls are disjoint one obtains

$$S_M := \sum_{j=0}^M \rho_j^{n-1} \leq c \|f\|_{L^p(\mathbb{R}^n)} \left(\sum_{j=0}^M k_j^{2p'} \rho_j^n \right)^{1/p'}.$$

For any $p \in (1, \infty)$ there is δ_p such that $r^{1/2} |\log_2 r|^{2p'} \leq 1$ for all $r \in (0, \delta_p)$. Therefore for all $\delta \leq \delta_p$ one obtains

$$S_M \leq c \|f\|_{L^p(\mathbb{R}^n)} \delta^{1/(2p')} S_M^{1/p'}. \quad (4.8)$$

By collecting (4.7) and (4.8) we conclude

$$\mathcal{H}_{10\delta}^{n-1}(F) \leq c \|f\|_{L^p(\mathbb{R}^n)}^p \delta^{p/(2p')},$$

therefore with $\delta \rightarrow 0$ we obtain $\mathcal{H}^{n-1}(F) = 0$. \square

Proof of Theorem 4.1. Let $x \in \Omega \setminus \Theta_u$, by [3, Corollary 6.7] for any $r > 0$ there is $a_{x,r} \in \mathbb{R}^n$ such that

$$\limsup_{r \rightarrow 0} \frac{1}{r^n} \int_{B_r(x)} |u(y) - a_{x,r}| dy = 0. \quad (4.9)$$

In the rest of the proof we will show that $\lim_{r \rightarrow 0} a_{x,r}$ exists for \mathcal{H}^{n-1} -almost every $x \in \Omega \setminus \Theta_u$. In view of (4.9) it is actually sufficient to prove the claim for the subsequence $r_k = 2^{-k}$.

Let η be as in Lemma 4.2 and let

$$\Omega_k := \{x \in \Omega : B_{r_k}(x) \subset \Omega \text{ and } \mathcal{H}^{n-1}(J_u \cap B_{r_k}(x)) \leq \eta r_k^{n-1}\}.$$

We also introduce the set

$$F := \left\{ x \in \mathbb{R}^n : \sum_{k \in \mathbb{N}} \frac{1}{r_k^{n-1}} \int_{B_{r_k}(x)} |e(u)| dy = \infty \right\}$$

and we fix $k \in \mathbb{N}$ and $x \in \bigcap_{h \geq k} \Omega_h \setminus (\Theta_u \cup F)$. By Lemma 4.2 for every $h \geq k$ there are an affine map $\varphi_h : \mathbb{R}^n \rightarrow \mathbb{R}^n$ and a set ω_h such that $\mathcal{L}^n(\omega_h) < 2^{-n-3} \mathcal{L}^n(B_{r_h})$ and

$$\int_{B_{r_h}(x) \setminus \omega_h} |u - \varphi_h| dy \leq cr_h \int_{B_{r_h}(x)} |e(u)| dy. \quad (4.10)$$

Lemma 4.3 yields

$$\begin{aligned} |\varphi_h(x) - a_{x,r_h}| &\leq \frac{c}{r_h^n} \int_{B_{r_h}(x) \setminus \omega_h} |a_{x,r_h} - \varphi_h| dy \\ &\leq \frac{c}{r_h^n} \int_{B_{r_h}(x) \setminus \omega_h} |a_{x,r_h} - u| dy + \frac{c}{r_h^n} \int_{B_{r_h}(x) \setminus \omega_h} |u - \varphi_h| dy. \end{aligned} \quad (4.11)$$

At the same time, using the triangle inequality, (4.10) implies

$$\int_{B_{r_{h+1}}(x) \setminus (\omega_h \cup \omega_{h+1})} |\varphi_h - \varphi_{h+1}| dy \leq cr_h \int_{B_{r_h}(x)} |e(u)| dy.$$

Lemma 4.3 now implies

$$\sum_h \|\varphi_h - \varphi_{h+1}\|_{L^\infty(B_{r_h}(x), \mathbb{R}^n)} \leq c \sum_h \frac{1}{r_h^{n-1}} \int_{B_{r_h}(x)} |e(u)| dy,$$

since $\mathcal{L}^n(B_{r_{h+1}} \setminus (\omega_h \cup \omega_{h+1})) \geq (1 - 2^{-3} - 2^{-n-3}) \mathcal{L}^n(B_{r_{h+1}}) \geq \frac{3}{4} \mathcal{L}^n(B_{r_{h+1}})$ and the maps φ_h are affine. Recalling that $x \notin F$, we have that the series $\sum_h |\varphi_h - \varphi_{h+1}|(x)$ converges and we can define $\tilde{u}(x) := \lim_{h \rightarrow \infty} \varphi_h(x) \in \mathbb{R}^n$. Then

$$\begin{aligned} &\frac{1}{r_h^n} \int_{B_{r_h}(x)} |u(y) - \tilde{u}(x)| dy \\ &\leq \frac{1}{r_h^n} \int_{B_{r_h}(x)} |u(y) - a_{x,r_h}| dy + c|a_{x,r_h} - \varphi_h(x)| + c|\varphi_h(x) - \tilde{u}(x)| \\ &\leq \frac{1}{r_h^n} \int_{B_{r_h}(x)} |u(y) - a_{x,r_h}| dy + \frac{c}{r_h^{n-1}} \int_{B_{r_h}(x)} |e(u)| dy + c|\varphi_h(x) - \tilde{u}(x)|, \end{aligned}$$

where we have used (4.11), (4.10). The first term converges to zero by (4.9), the second one by the fact that $x \notin F$, and the third one by the definition of \tilde{u} . Therefore $x \in \Omega \setminus S_u$. We conclude that

$$S_u \subset \Theta_u \cup F \cup \left(\Omega \setminus \bigcup_k \bigcap_{h \geq k} \Omega_h \right).$$

We finally show that

$$\Omega \setminus \bigcup_k \bigcap_{h \geq k} \Omega_h \subset J_u \cup N \quad (4.12)$$

for some \mathcal{H}^{n-1} -null set N , from which we can conclude $S_u \subset \Theta_u \cup F \cup N$. Since $\mathcal{H}^{n-1}(J_u) < \infty$ by [4, Th. 2.56] there is a set N with $\mathcal{H}^{n-1}(N) = 0$ such that

$$\limsup_{r \rightarrow 0} \frac{\mathcal{H}^{n-1}(J_u \cap B_r(x))}{r^{n-1}} = 0 \text{ for all } x \in \Omega \setminus (J_u \cup N).$$

In particular, for any such x there is a k such that $x \in \Omega_h$ for any $h \geq k$, so that formula (4.12) holds. From $e(u) \in L^p(\Omega; \mathbb{R}^{n \times n})$, Lemma 4.4 guarantees that $\mathcal{H}^{n-1}(F) = 0$, and the proof is concluded. \square

5 Discussion

As mentioned in the introduction, in the variational formulation of some mathematical problems in fracture mechanics, the natural analytical framework is given by the set $SBD^p(\Omega)$ defined in (1.3). Due to the regularity generated by the higher integrability of the strain and the finite \mathcal{H}^{n-1} -measure of the jump set, it has been conjectured that $SBD^p(\Omega)$ functions might have in fact bounded variation. In this case one would have in particular $SBD^p(\Omega) \subset SBV(\Omega; \mathbb{R}^n)$, since Alberti's rank one theorem [1, 2] implies $|D^c u|(\Omega) \leq \sqrt{2}|E^c u|(\Omega)$ for each $u \in BV(\Omega; \mathbb{R}^n)$. Moreover one could reasonably expect that the inclusion above is related to the validity of a Korn's type inequality involving the L^1 -norm of ∇u , the L^p -norm of $e(u)$, and $\mathcal{H}^{n-1}(J_u)$. A Korn's type inequality for ∇u alone is, however, not enough to guarantee that a field u in $SBD^p(\Omega)$ has bounded variation, since an equivalent of Alberti's rank one theorem in BD has not been proved (nor disproved).

In light of the results described in the previous sections, we are now in the position to discuss the possible optimality of the immersion above. First of all let us recall that a generic function $u \in SBD(\Omega)$ has not necessarily bounded variation, even in the case in which u has no jumps. This follows from the counterexample to Korn's inequality in $W^{1,1}$ built in [31], see [3, Example 7.7]. A similar idea is the starting point of the construction presented in Section 3, developed starting from [19, Theorem 1]. Indeed, we have shown that, if no bound on the size of the jump set is given, not even the condition $e(u) = 0$ \mathcal{L}^n -a.e. guarantees that a function $u \in SBD(\Omega)$ has bounded variation. Analogously, we have constructed a function $u \in BD(\Omega) \setminus BV(\Omega; \mathbb{R}^n)$ with $Eu = E^c u$.

On the contrary, in some sense one cannot expect an inclusion stronger than $SBD^p(\Omega) \subset SBV(\Omega; \mathbb{R}^n)$, to be precise one cannot hope for a higher integrability of the gradient, as Example 2.1 shows.

To conclude this discussion about the connections between SBD^p and BV , we mention the result proved in [18, Theorem A.1]. The authors show that any $u \in SBD(\Omega)$ with $e(u) = 0$ \mathcal{L}^n -a.e. and $\mathcal{H}^{n-1}(J_u) < \infty$ has in fact a precise structure, it is a Caccioppoli-affine function. Thanks to the result proved in Section 2 we thus infer that it has actually (generalized) bounded variation.

Acknowledgments

This work was partially supported by the Deutsche Forschungsgemeinschaft through the Sonderforschungsbereich 1060 “*The mathematics of emergent effects*”, project A6.

F. Iurlano thanks the University of Florence for the warm hospitality of the DiMaI “Ulisse Dini”, where part of this work was carried out during the winter of 2015.

Part of this work was conceived when M. Focardi was visiting the University of Bonn in winter 2015. He thanks the Institute for Applied Mathematics for the hospitality and the stimulating scientific atmosphere provided during his stay.

M. Focardi and F. Iurlano are members of the Gruppo Nazionale per l’Analisi Matematica, la Probabilità e le loro Applicazioni (GNAMPA) of the Istituto Nazionale di Alta Matematica (INdAM).
